

## REACTIONS OF ALKENES.

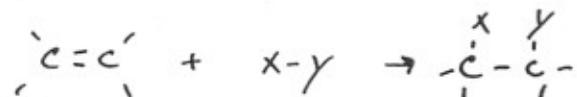

IN A WORD, ADDITION

ELECTROPHILES WILL ADD TO THE DOUBLE BOND TO FORM ADDITION PRODUCTS.

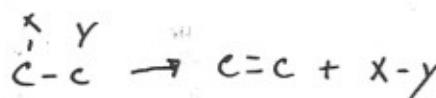

THE FORMATION OF 2 NEW  $\sigma$  BONDS IS EXOTHERMIC

IN MANY WAYS ADDITION IS THE REVERSE OF ELIMINATION

ADDITION

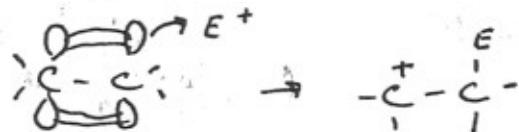

ELIMINATION

## ELECTROPHILIC ADDITION TO ALKENES

- 1) STRONG ELECTROPHILES PULL THE ELECTRONS OUT OF A  $\pi$  BOND  
TO FORM A NEW  $\sigma$  BOND

A CARBOCATION RESULTS

- 2) THE CARBOCATION THEN DOES WHAT CARBOCATIONS DO

REACT WITH A NUCLEOPHILE AS IN A SN1 REACTION

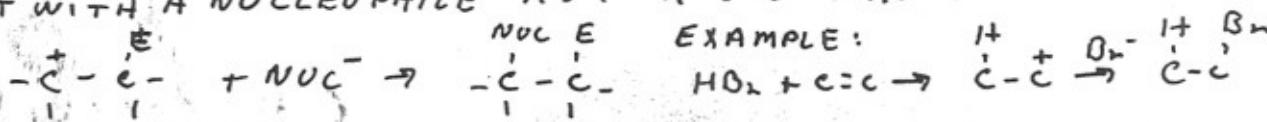

TABLE 8-1 Types of Additions to Alkenes

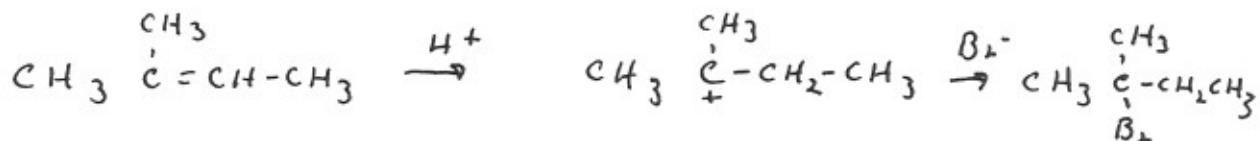

$\text{C}=\text{C}$	Type of Addition [Elements Added] <sup>a</sup>	Product
$\xrightarrow[\text{H}_2\text{O}]{}$ hydration	$\begin{array}{c} \text{H} \quad \text{OH} \\   \quad   \\ \text{C} \quad \text{C} \end{array}$	$\xrightarrow[\text{[X}_2\text{], an oxidation}]{}$ halogenation $\begin{array}{c} \text{X} \quad \text{X} \\   \quad   \\ \text{C} \quad \text{C} \end{array}$
$\xrightarrow[\text{H}_2, \text{ a reduction}]{}$ hydrogenation	$\begin{array}{c} \text{H} \quad \text{H} \\   \quad   \\ \text{C} \quad \text{C} \end{array}$	$\xrightarrow[\text{[HOX], an oxidation}]{}$ halohydrin formation $\begin{array}{c} \text{X} \quad \text{OH} \\   \quad   \\ \text{C} \quad \text{C} \end{array}$
$\xrightarrow[\text{[HOOH], an oxidation}]{}$ hydroxylation	$\begin{array}{c} \text{OH} \quad \text{OH} \\   \quad   \\ \text{C} \quad \text{C} \end{array}$	$\xrightarrow[\text{[HX]}]{}$ HX addition $\begin{array}{c} \text{H} \quad \text{X} \\   \quad   \\ \text{C} \quad \text{C} \end{array}$
$\xrightarrow[\text{[O}_2\text{], an oxidation}]{}$ oxidative cleavage	$\begin{array}{c} \text{C}=\text{O} \quad \text{O}=\text{C} \\   \quad   \\ \text{C} \quad \text{C} \end{array}$	$\xrightarrow[\text{[CH}_2\text{]}]{}$ cyclopropanation $\begin{array}{c} \text{H} \quad \text{H} \\   \quad   \\ \text{C} \quad \text{C} \\   \quad   \\ \text{C} \quad \text{C} \end{array}$
$\xrightarrow[\text{[O], an oxidation}]{}$ epoxidation	$\begin{array}{c} \text{O} \\   \\ \text{C} \quad \text{C} \end{array}$	

<sup>a</sup>These are not the reagents used but simply the groups that appear in the product.

## ADDITION OF HYDROGEN HALIDES

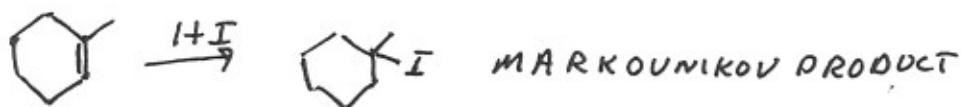

HYDROGEN HALIDES ADD TO DOUBLE BONDS REGIOSPECIFICALLY

A PROTON ADDS FIRST AND FORMS THE MOST STABLE CATION

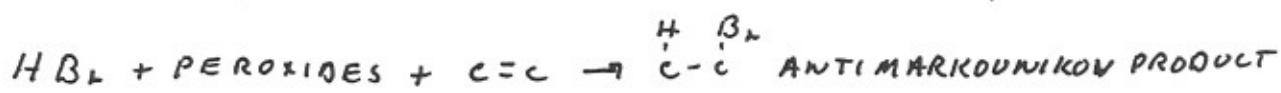

MARKOVNIKOV'S RULE SAYS THAT THE PROTON WILL ADD TO THE CARBON THAT ALREADY HAS THE MOST HYDROGENS - THIS LEAVES THE CATION ON THE CARBON WITH THE MOST CARBONS WHICH IS THE MOST STABLE CATION

HCl AND HI REACT THE SAME WAY

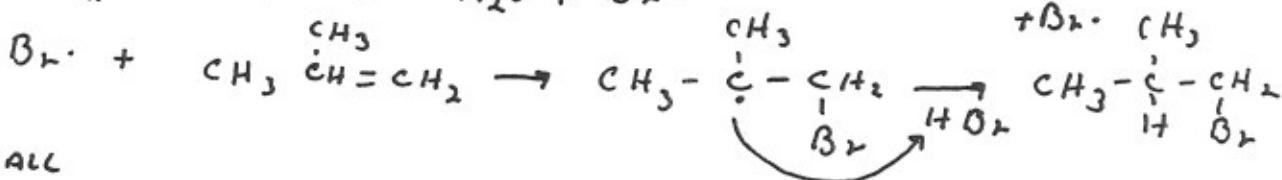

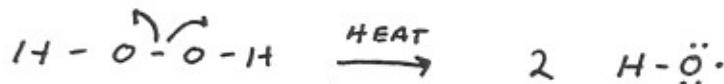

## FREE RADICAL ADDITION

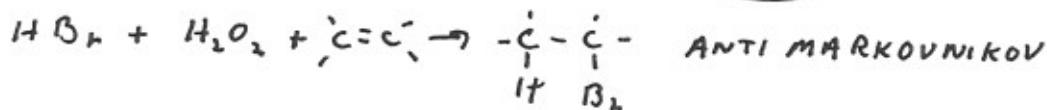

WITH FREE RADICAL ADDITION OF HBr THE ELECTROPHILE IS Br<sup>-</sup>. IT ADDS THE SAME WAY, BUT IT ADDS FIRST, A H<sup>.</sup> SECOND. THIS RESULTS IN THE ANTI-MARKOVNIKOV PRODUCT (ONLY HBr DOES THIS)

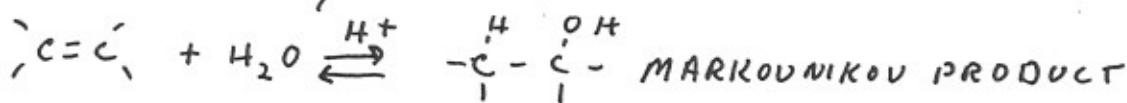

PEROXIDES ARE OFTEN USED AS FREE RADICAL INITIATORS

OVERALL

## ADDITION OF WATER: HYDRATION

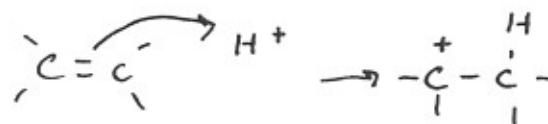

$\longrightarrow$  HYDRATION

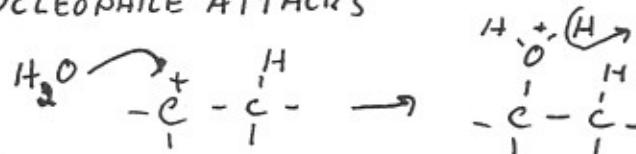

DEHYDRATION  $\longleftarrow$

HYDRATION AND DEHYDRATION REALLY ARE REVERSIBLE  
THE MECHANISM IS THE REVERSE OF CHAPTER 7

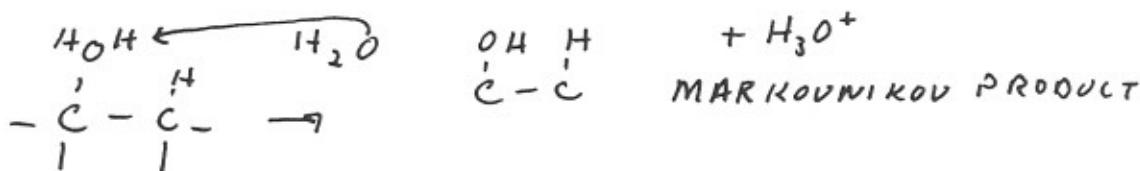

1) PROTONATION

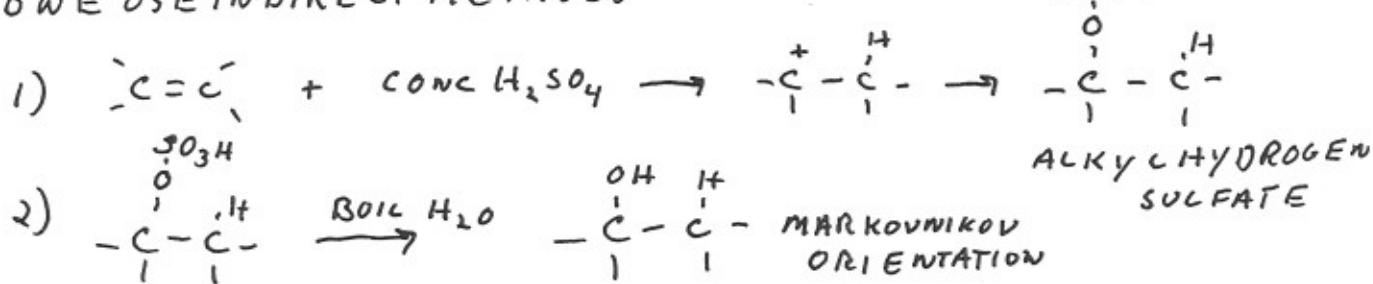

2) NEAREST NUCLEOPHILE ATTACKS

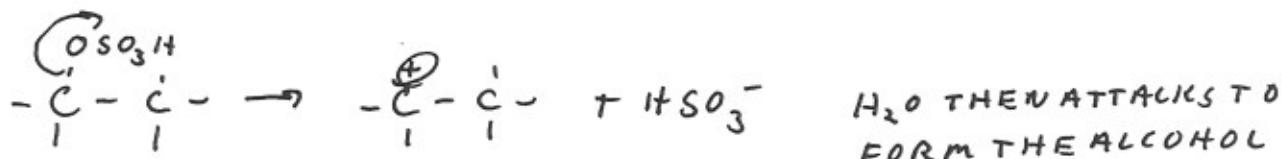

3) LOSS OF A H<sup>+</sup> TO WATER

HOWEVER, MANY ALKENES ARE INSOLUBLE IN H<sub>2</sub>O, OR THE EQUILIBRIUM STRONGLY DISFAVORS THE ALCOHOL  
SO WE USE INDIRECT METHODS

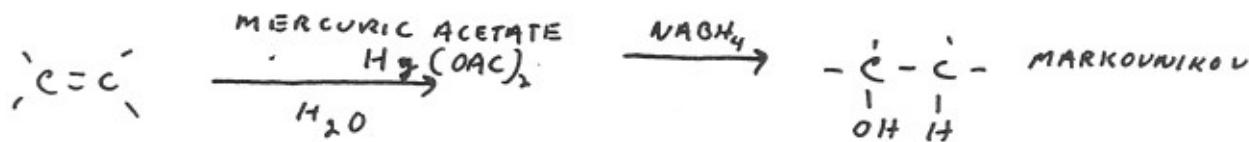

THIS STEP IS AN S<sub>N</sub>1 REACTION, HSO<sub>4</sub><sup>-</sup> IS THE LEAVING GROUP

MOST USEFUL OF ALL (HIGH YIELD, NO C<sup>+</sup> REARRANGEMENTS)

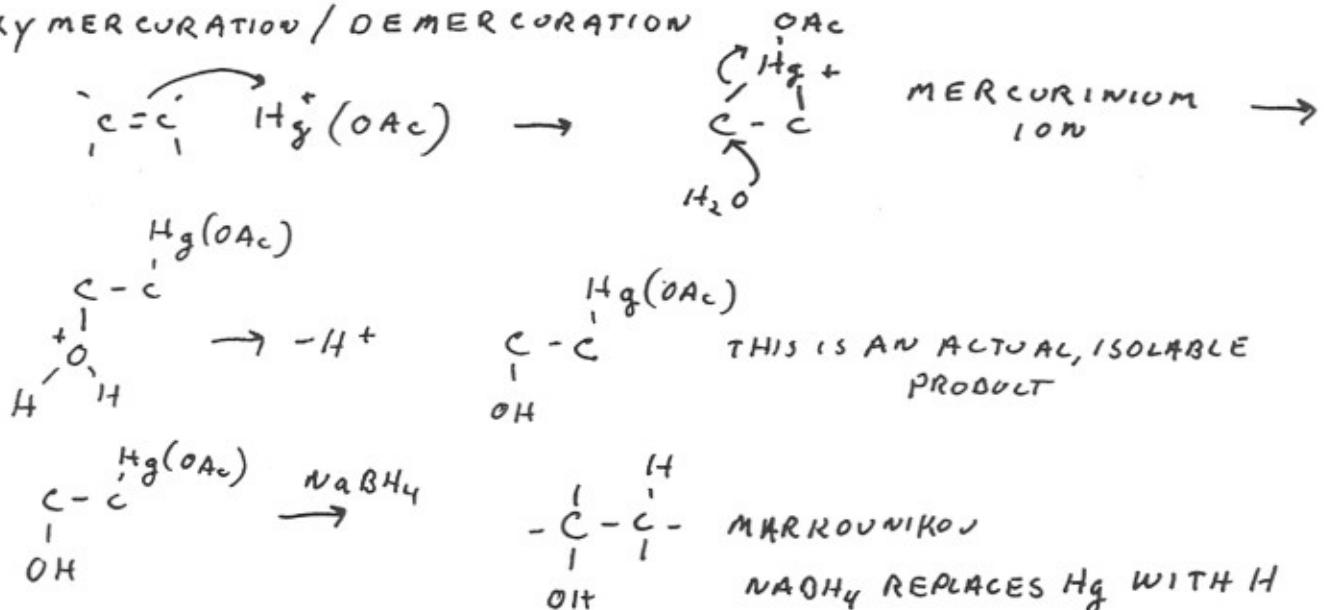

IS OXYMERCURATION/DEMERCURATION

ITS A TWO STEP REACTION WITH SOME EXOTIC REAGENTS, INTERMEDIATES THAT PRODUCES A MARKOVNIKOV PRODUCT WITHOUT REARRANGEMENTS

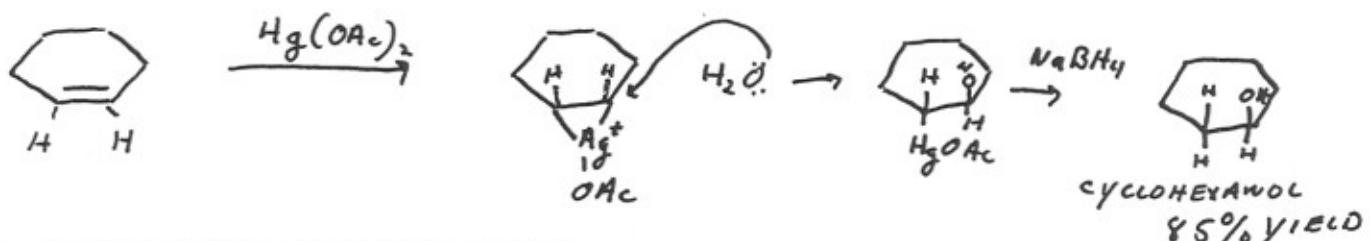

NaBH<sub>4</sub> IS SODIUM BOROHYDROIDE, A REDUCING AGENT

## OXYMERCURATION / DEMERCURATION

THIS REACTION IS STEREO SPECIFIC

THE CYCLIC STRUCTURE OF THE MERCURY PRODUCT FORCES "ANTI" ADDITION OF OH

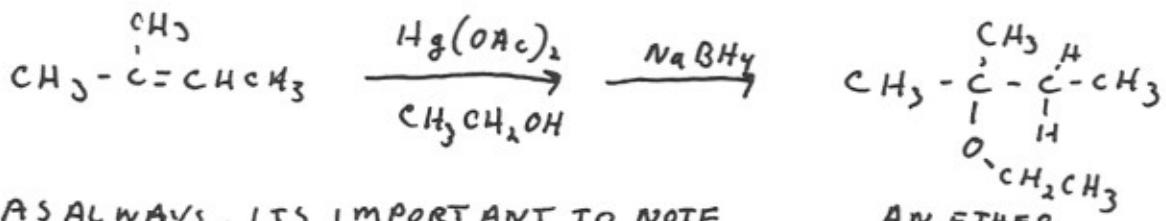

## ALKOXY MERCURATION/DEMERCURATION

JUST PICTURE THE ABOVE REACTION IN AN ALCOHOL SOLVENT  $\text{R}-\text{OH}$  INSTEAD OF WATER

YOU GET THE SAME TYPE OF PRODUCT WITH A CARBON GROUP ATTACHED TO THE OXYGEN - AN ETHER

THIS IS ADDITION OF AN ALCOHOL TO THE DOUBLE BOND  $\text{RO}-\text{H}$

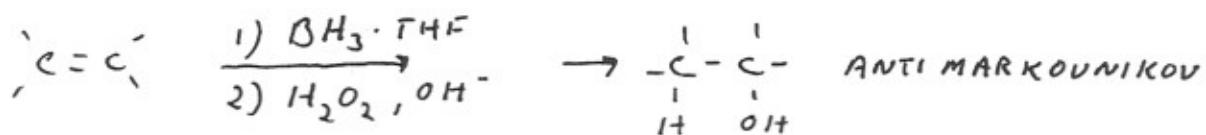

AS ALWAYS, IT'S IMPORTANT TO NOTE THE DANGER FROM MERCURY TOXICITY

IN ALL ITS FORMS, METAL, ALKYL MERCURY ( $\text{Hg}(\text{CH}_3)_2$ ) OR MERCURIC SALTS LIKE  $\text{Hg}(\text{OAc})_2$ , MERCURY IS DANGEROUSLY TOXIC

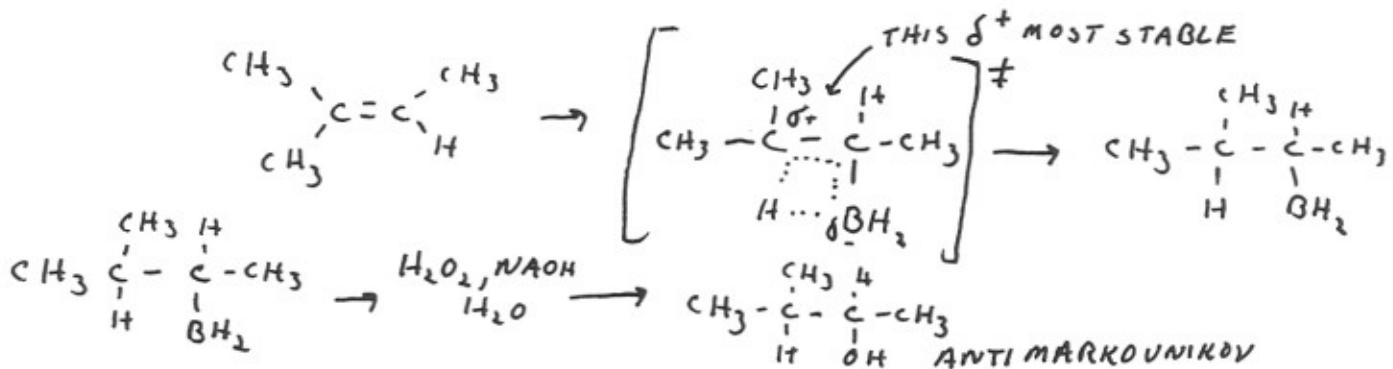

$\text{Hg}(\text{CH}_3)_2$  EVEN PENETRATES LATEX GLOVES!

## HYDROBORATION / OXIDATION

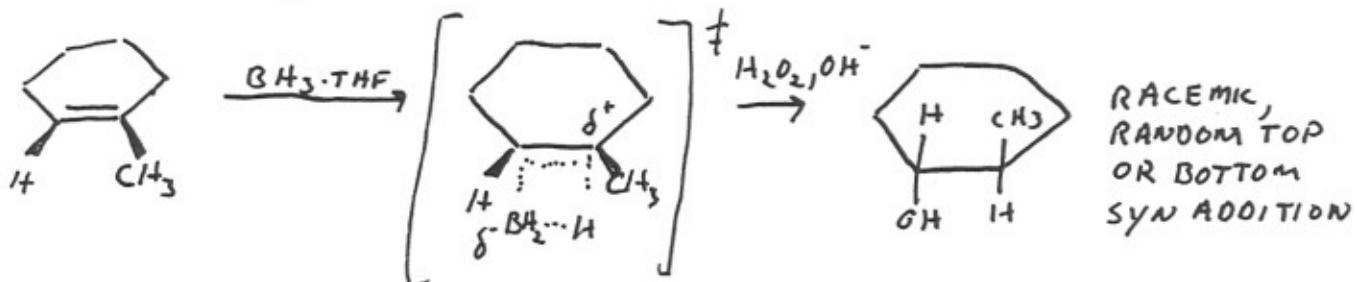

MAKE ANTI-MARKOUMIKOV ALCOHOLS FROM ALKENES

THIS REACTION INVOLVES A CYCLIC INTERMEDIATE:

THE STEREO-SPECIFICITY OF THE REACTION IS SYN ADDITION

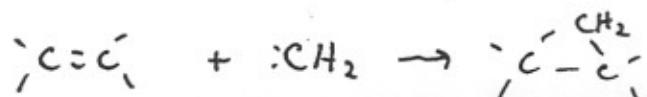

## HYDROGENATION

REDUCTION OF AN ALKENE (ALKYNE, C=O) WITH H<sub>2</sub>/CATALYST

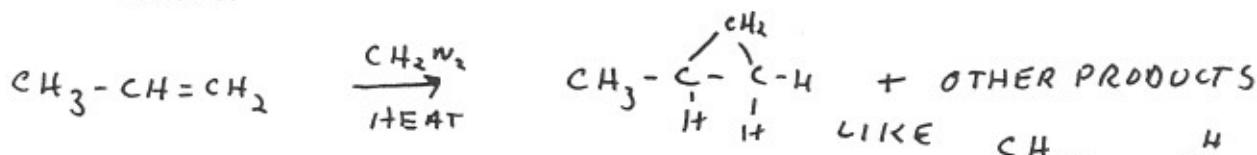

HYDROGEN ABSORBED ON A METAL SURFACE ADDS TO ONE "FACE" OF THE DOUBLE BOND, USUALLY RANDOM "FACE", BUT OCCASIONALLY ONE FACE IS PREFERRED FIG 5-23  
IT IS ALSO POSSIBLE TO USE CHIRAL CATALYSTS FOR ASYMMETRIC INDUCTION Pg 219

## CARBENES

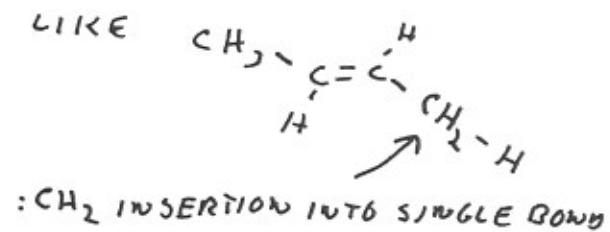

:CH<sub>2</sub> IS METHYLENE, THE SIMPLEST CARBENE. IT ADDS TO DOUBLE BONDS TO MAKE CYCLOPROPANES

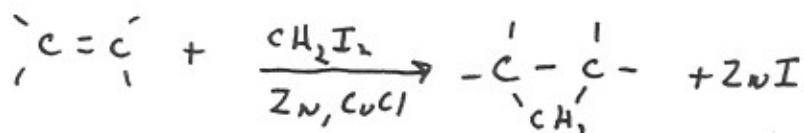

THE ORIGINAL CARBENE REACTION USES DIAZOMETHANE  $\text{CH}_2\text{N}_2$

THIS, PLUS THE TOXIC, EXPLOSIVENESS OF  $\text{CH}_2\text{N}_2$   
LIMITS ITS USEFULNESS

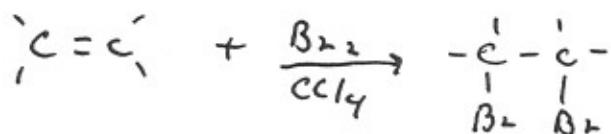

A BETTER REACTION IS THE SIMMONS-SMITH REACTION

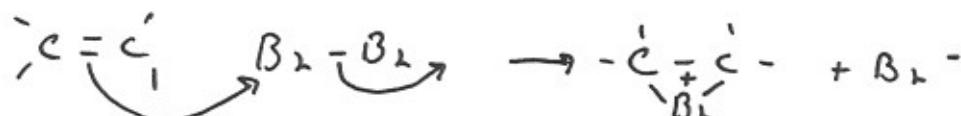

THIS IS THE PREFERRED METHOD  
FOR MAKING CYCLOPROPANES

ADDITION OF HALOGENS

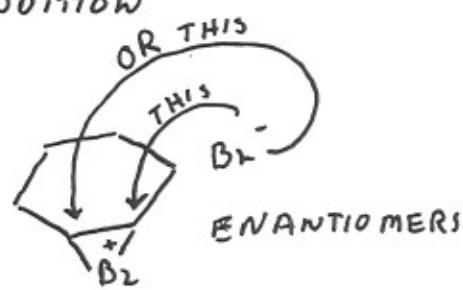

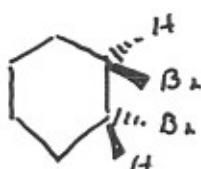

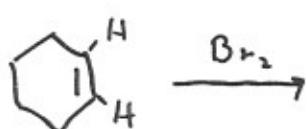

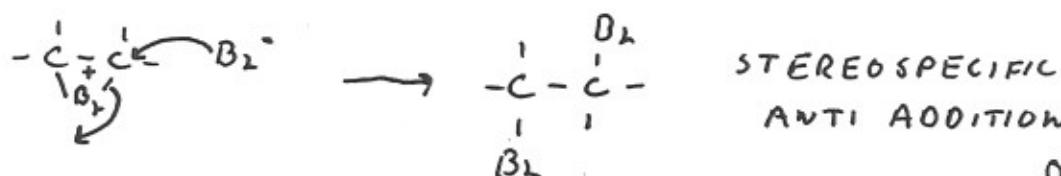

PG 355 SHOWS A PICTURE OF RED/BROWN BROMINE ( $\text{Br}_2$ )  
BEING "DECOLORIZED" BY AN ALKENE

THE MECHANISM OF THIS REACTION INVOLVES A "CYCLIC BROMONIUM ION"  
OR CYCLIC "HALONIUM" ION IF  $\text{Cl}_2$  OR  $\text{I}_2$  ARE USED

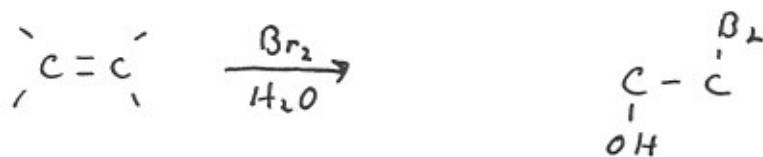

THIS CYCLIC ION IS OPENED BY BROMIDE

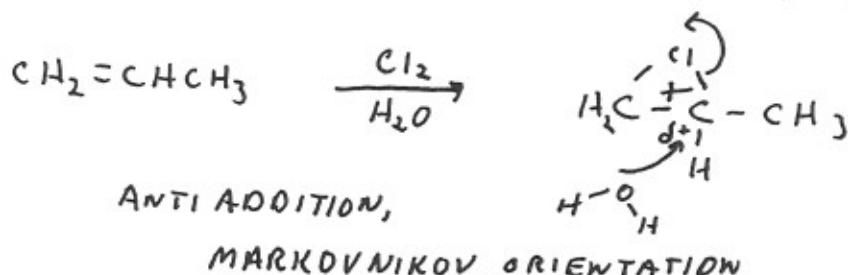

## HALOHYDRINS

HALOGENS PLUS WATER ADD TO ALKENES TO FORM HALOHYDRINS

A HALONIUM ION IS INVOLVED, SO STEREOCHEMISTRY IS ANTI  
MARKOVNIKOV ORIENTATION IS ALSO OBSERVED

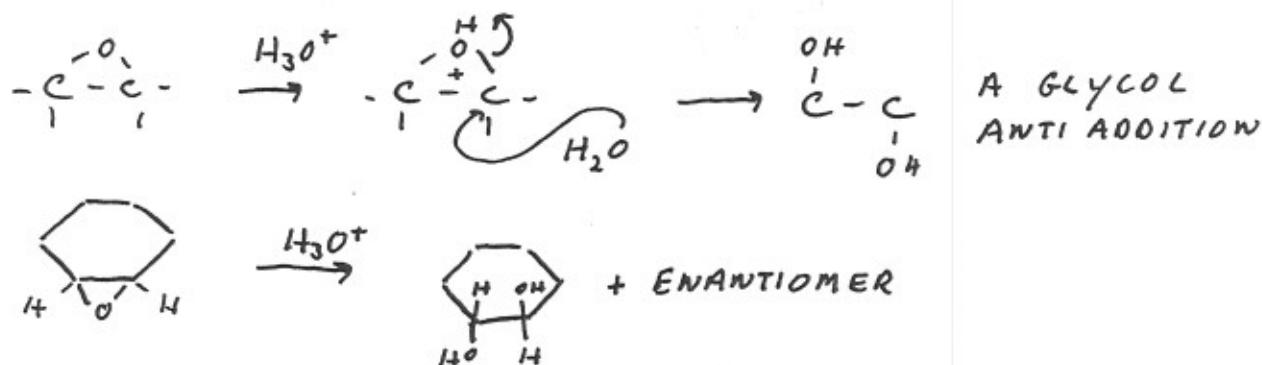

WHILE THE WHOLE RING BEARS A + CHARGE,  
MORE PARTIAL + IS ON THE MORE SUBSTITUTED CARBON

## EPOXIDATION

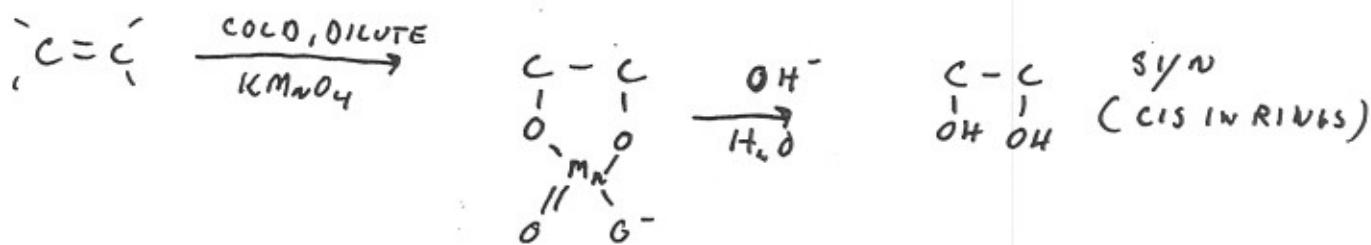

## ACID CATALYZED OPENING OF EPOXIDES

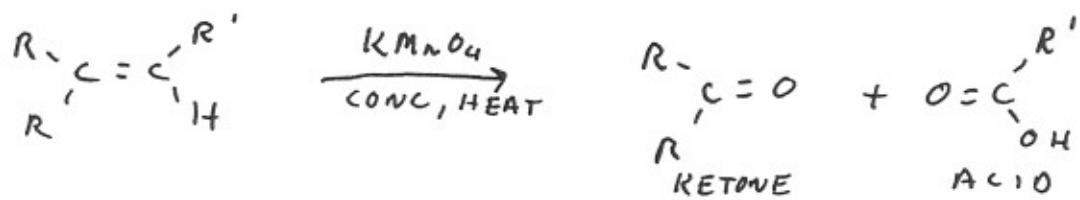

WE CAN ALSO MAKE SYN GLYCOLS WITH  $\text{OsO}_4$ , OSMIUM TETROXIDE OR  $\text{KMnO}_4$  (COLD, DILUTE) POTASSIUM PERMANGANATE

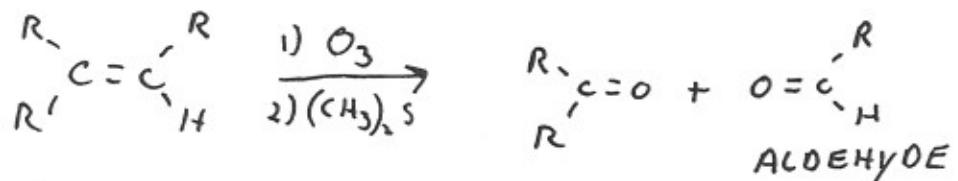

A CYCLIC INTERMEDIATE ENSURES SYN HYDROXYLATION

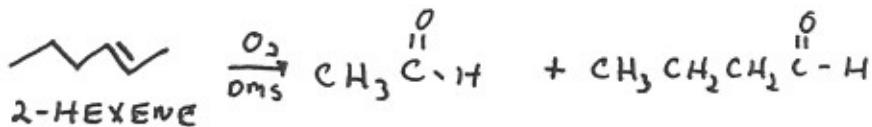

OXIDATIVE CLEAVAGE  $C=C \rightarrow C=O + O=C$

OR OZONOLYSIS (MILDER)

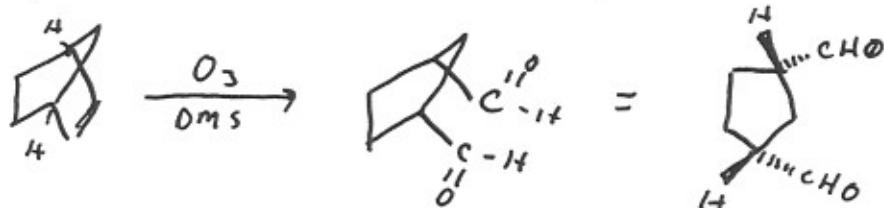

EXAMPLES

ANY  $C=C$  IS REPLACED BY  $C=O$  AND  $C=O$

THE OZONOLYSIS INTERMEDIATE IS CYCLIC, SYN PRODUCTS RESULT

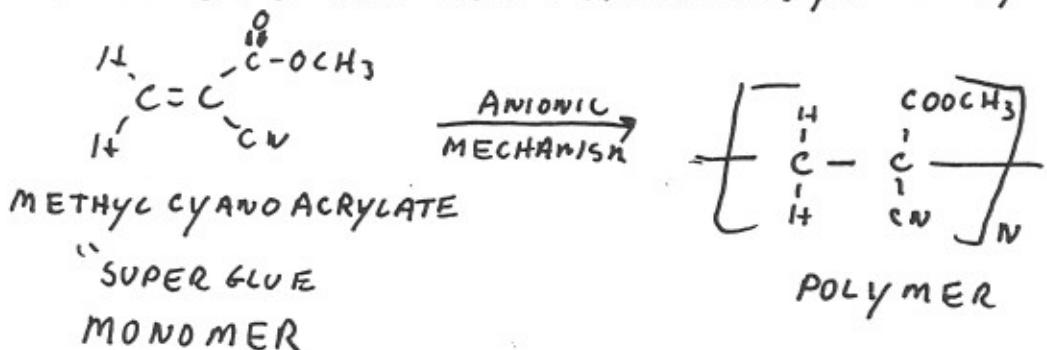

POLYMERIZATION

IT'S ARGUABLY THE MOST IMPORTANT REACTION OF ALKENES / EPOXIDES

POLYMERS ARE LARGE ( $MW 10,000 \rightarrow >1,000,000$ ) MOLECULES  
MADE FROM REPEATING UNITS (MONOMERS)

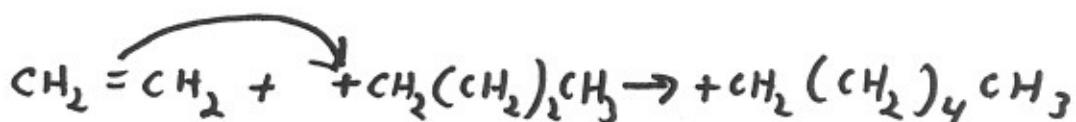

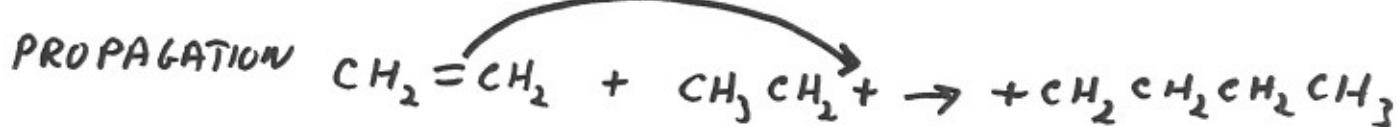

MECHANISMS ARE CHAIN REACTIONS, ANIONIC, CATIONIC, FREE RADICAL

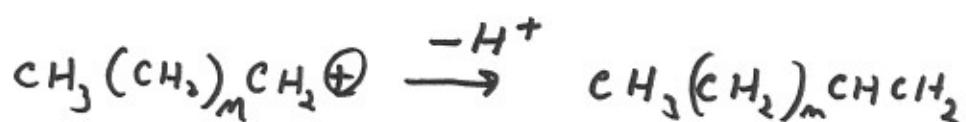

# CATIONIC POLYMERIZATION

ACID CATALYSED, CATIONIC INTERMEDIATES

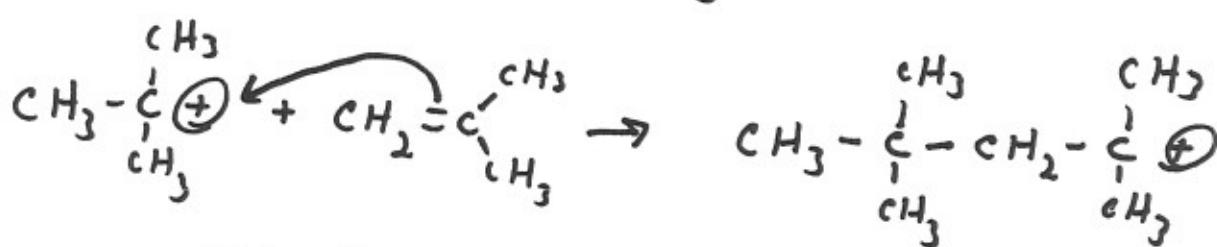

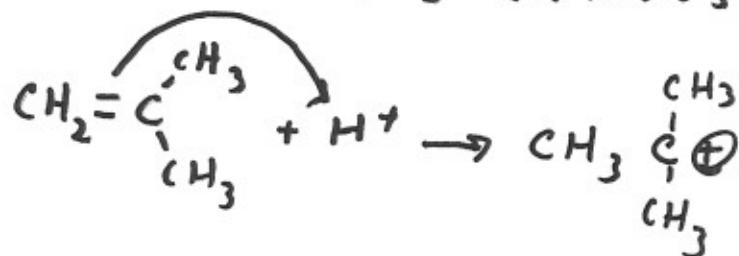

ANOTHER EXAMPLE OF ELECTROPHILIC ADDITION  
TO AN ALKENE:

THE GROWING CHAIN TERMINATES WHEN A CATION  
ELIMINATES A PROTON

WORKS BEST WITH  $3^\circ$  CATIONS

THIS POLYMER IS CALLED BUTYL RUBBER
